Coding & Solution

Treavue — Personalized Travel Itinerary Planner

Project documentation prepared for portfolio and repository use

Implemented areas

- React/Vite/TypeScript frontend and trip workflow.
- FastAPI backend with destination and itinerary endpoints.
- Trip CRUD endpoints backed by Supabase.
- Trip object stored as JSONB with metadata columns.
- Browser localStorage fallback and sync warnings.
- Preference-aware itinerary schedule ranking using existing data.
- Tests for backend behavior and existing functionality.

Representative trip storage mapping

Database column	Meaning
id	**Stable trip identifier**
name	**Trip title/name**
destination	**Destination identifier**
trip_data	**Full nested trip object as JSONB**
created_at / updated_at	**Database timestamps where configured**

Error handling

Storage configuration or request failures should return controlled API errors and should not silently erase local trip data.

Reproducibility

Use the documented local backend and frontend commands in the project's README/notes. Keep actual .env files private.

Security caveat

CRUD functionality alone is not equivalent to secure multi-user access. Confirm verified authentication and owner enforcement before deployment.
